(54) Strip casting apparatus

(57) Twin roll caster for casting metal strip. Metal is delivered through a distributor (18) and delivery nozzle (19) between a pair of casting rolls (16) to form a casting pool (30) supported on rolls (16) and confined by end plates (56). Rolls (16) are rotated to deliver cast strip downwardly from the nip between them. Rolls (16) are mounted on carriers (104) moveable to allow rolls (16)

to move bodily toward and away from one another. Biasing units (110, 111) act on the roll carriers (104) to force them against lateral stops (107) and to provide roll biasing forces.

Stops (107) are adjustable to set the width of the nip between the rolls (16). Biasing units (110) comprise biasing springs (112) whereas biasing units (111) comprise hydraulic actuators (113).

FIG. 2.

Printed by Laser 7500 (FAPS, FR)

Description

BACKGROUND OF THE INVENTION

[0001] This invention relates to the casting of metal strip, it has particular application to the casting of metal strip by continuous casting in a twin roll caster.

[0002] In a twin roll caster molten metal is introduced between a pair of contra-rotated horizontal casting rolls which are cooled so that metal sheet solidifies on the moving roll surfaces and are brought together at the nip between them to produce a solidified strip product delivered downwardly from the nip between the rolls. The term "nip" is used herein to refer to the general region at which the rolls are closest together. The molten metal may be poured from a ladle into a smaller vessel or series of smaller vessels from which it flows through a metal delivery nozzle located above the nip so as to direct it into the nip between the rolls, so forming a casting pool of molten metal supported on the casting surfaces of the rolls, immediately above the nip and extending along the length of the nip. This casting pool is usually confined between side plates or dams held in sliding engagement with end surfaces of the rolls so as to dam the two ends of the casting pool against outflow, although alternative means such as electromagnetic barriers have also been proposed.

[0003] The setting up and adjustment of the casting rolls in a twin roll caster is a significant problem. The rolls must be accurately set to properly define an appropriate width for the nip, generally the order of only a few millimetres, and there must also be some means for allowing at least one of the rolls to move outwardly against a biasing force to accommodate fluctuations in strip thickness particularly during start up. Previously proposed arrangements have employed roll mounting and biasing means in which require relative sliding movement between separate components at several locations, resulting in several sources of friction loading which interferes with accurate positioning of the rolls and accurate measurement of the roll biasing forces. Moreover, with the previous arrangements it has not been possible to provide preloading roll biasing forces which can be accurately set prior to casting and it has been necessary to wait for metal to pass through the rolls to develop reactive forces resisting roll separation in order to generate appropriate roll biasing forces. The present invention provides a novel roll biasing system which minimises the sources of friction during operation and which enables the preloading of the roll biasing forces prior to casting.

SUMMARY OF THE INVENTION

[0004] According to the invention there is provided apparatus for continuously casting metal strip comprising a pair of parallel casting rolls forming a nip between them, metal delivery means to deliver molten metal into

the nip between the rolls to form a casting pool of molten metal supported on casting roll surfaces, immediately above the nip, pool containing means to confine the molten metal in the casting pool against outflow from the area of the nip, and roll driven means to drive the casting rolls in counter rotational directions to produce a solidified strip of metal delivered downwardly from the nip, wherein at least one of the casting rolls is mounted on a pair of moveable roll carriers which allow that one roll to move bodily toward and away from the other roll, wherein there is an adjustable stop means to limit inward bodily movement of said one roll toward the other, wherein there is a pair of roll biasing units acting on each of the pair of moveable roll carriers to bias said one roll bodily inwardly toward the other roll, and wherein each roll biasing unit comprises a thrust transmission structure connected to the respective roll carrier, a thrust reaction structure having a set position, thrust means acting between the thrust reaction structure and the thrust transmission structure to exert a thrust on the thrust transmission structure to bias the respective roll carrier inwardly against the limit imposed by the stop means.

[0005] Preferably the thrust transmission structure incorporates a load cell to monitor the thrust transmitted thereby without any friction generating movement within that structure.

[0006] The thrust means may comprise a spring acting between the thrust reaction structure and the thrust transmission structure.

[0007] Alternatively or in addition the thrust means may comprise a pressure fluid actuator means.

[0008] If the thrust means consists solely of a pressure fluid actuator means, the thrust reaction structure may be permanently fixed in said set position. However, in the case where the thrust means comprises a spring, the thrust reaction structure may be adjustable in position to vary said set position whereby to vary the biasing force generated by the spring.

[0009] The casting rolls may each be mounted on a pair of moveable roll carriers so as to be bodily moveable toward and away from the other roll and the adjustable stop means may then limit inward bodily movement of both of the rolls.

[0010] In that case the said pair of roll biasing units may be one of two such pairs acting on the pairs of roll carriers to bias both of the rolls inwardly against the limit established by the stop means.

[0011] The adjustable stop means may be disposed beneath the nip and between the roll carriers to serve as a spacer stop for engagement with the roll carriers to pre-set the minimum width of the nip between the rolls and adjustable in width to vary the minimum width of the nip.

[0012] The roll carriers may comprise a pair of roll end support structures for each of the rolls disposed generally beneath the ends of the respective roll. Each pair of roll end support structures may carry journal bearings

mounting the respective roll ends for rotation about a central roll axis.

[0013] The adjustable stop means may comprise a pair of adjustable stops disposed one between each of the pairs of roll end support structures at the two ends of the roll assembly.

[0014] Each adjustable stop may serve as a centering stop disposed about a central vertical plane through the nip between the rolls and actuatable such that it can be expanded and contracted by equal movements to either side of the central plane so as to maintain equal minimum spacing of the rolls from the central plane.

[0015] Each central stop may be comprised of an expansible and contractible mechanical jack. Each jack may for example be screw or worm driven for adjustment.

[0016] The casting rolls and roll carriers may be mounted on a roll module installed in and removable from the caster as a unit. In that case, the thrust transmission structure of each biasing unit may be disconnectable from the respective roll carrier to enable the module to be removed without removing or dismantling the roll biasing units.

[0017] In apparatus in accordance with the invention in which both of the casting rolls are biased by respective pairs of biasing units, the biasing units acting on one of the rolls may have thrust means in the form of springs whereas the biasing units acting on the other roll may have thrust means in the form of pressure fluid actuators whereby the apparatus can be operated in alternative modes in which one of the rolls is restrained against laterally movement and the other is moveable laterally against either spring biasing forces or biasing forces generated by the pressure fluid actuators.

BRIEF DESCRIPTION OF THE DRAWINGS

[0018] In order that the invention may be fully explained one particular embodiment will be described in some detail with reference to the accompanying drawings in which:

Figure 1 is a vertical cross section through a strip caster constructed in accordance with the present invention.

Figure 2 is an enlargement of part of Figure 1 illustrating important components of the caster.

Figure 3 is a longitudinal cross section through important parts of the caster.

Figure 4 is an end elevation of the caster.

Figures 5, 6 and 7 show the caster in varying conditions during casting and during removal of the roll module from the caster.

Figure 8 is a vertical cross-section through a roll biasing unit incorporating a roll biasing spring; and Figure 9 is a vertical cross-section through a roll biasing unit incorporating a pressure fluid actuator.

DESCRIPTION OF PREFERRED EMBODIMENT

[0019] The illustrated caster comprises a main machine frame 11 which stands up from the factory floor (not shown) and supports a casting roll module in the form of a cassette 13 which can be moved into an operative position in the caster as a unit but can readily be removed when the rolls are to be replaced. Cassette 13 carries a pair of parallel casting rolls 16 to which molten metal is supplied during a casting operation from a ladle (not shown) via a tundish 17, distributor 18 and delivery nozzle 19 to create a casting pool 30. Casting rolls 16 are water cooled so that shells solidify on the moving roll surfaces and are brought together at the nip between them to produce a solidified strip product 20 at the roll outlet. This product may be fed to a standard coiler.

[0020] Casting rolls 16 are contra-rotated through drive shafts 41 from an electric motor and transmission mounted on the main machine frame. The drive shaft can be disconnected from the transmission when the cassette is to be removed. Rolls 16 have copper peripheral walls formed with a series of longitudinally extending and circumferentially spaced water cooling passages supplied with cooling water through the roll ends from water supply ducts in the roll drive shafts 41 which are connected to water supply hoses 42 through rotary glands 43. The roll may typically be about 500 mm diameter and up to 2000 mm long in order to produce strip product approximately the width of the rolls.

[0021] The ladle is of entirely conventional construction and is supported on a rotating turret whence it can be brought into position over the tundish 17 to fill the tundish. The tundish may be fitted with a sliding gate valve 47 actuatable by a servo cylinder to allow molten metal to flow from the tundish 17 through the valve 47 and refractory shroud 46 into the distributor 18.

[0022] The distributor 18 is also of conventional construction. It is formed as a wide dish made of a refractory material such as magnesium oxide (MgO). One side of the distributor 18 receives molten metal from the tundish 17 and the other side of the distributor 18 is provided with a series of longitudinally spaced metal outlet openings 52. The lower part of the distributor 18 carries mounting brackets 53 for mounting the distributor onto the main caster frame 11 when the cassette is installed in its operative position.

[0023] Delivery nozzle 19 is formed as an elongate body made of a refractory material such as alumina graphite. Its lower part is tapered so as to converge inwardly and downwardly so that it can project into the nip between casting rolls 16. Its upper part is formed with outwardly projecting side flanges 55 which locate on a mounting bracket 60 which forms part of the main frame 11.

[0024] Nozzle 19 may have a series of horizontally spaced generally vertically extending flow passages to produce a suitably low velocity discharge of metal throughout the width of the rolls and to deliver the molten

metal into the nip between the rolls without direct impingement on the roll surfaces at which initial solidification occurs. Alternatively, the nozzle may have a side continuous slot outlet to deliver a low velocity curtain of molten metal directly into the nip between the rolls and or it may be immersed in the molten metal pool.

[0025] The pool is confined at the ends of the rolls by a pair of side closure plates 56 which are held against stepped ends 57 of the rolls when the roll cassette is in its operative position. Side closure plates 56 are made of a strong refractory material, for example boron nitride, and have scalloped side edges to match the curvature of the stepped ends of the rolls. The side plates can be mounted in plate holders 52 which are movable by actuation of a pair of hydraulic cylinder units 53 to bring the side plates into engagement with the stepped ends of the casting rolls to form end closures for the molten pool of metal formed on the casting rolls during a casting operation.

[0026] During a casting operation the sliding gate valve 47 is actuated to allow molten metal to pour from the tundish 17 to the distributor 18 and through the metal delivery nozzle 19 whence it flows on to the casting rolls. The head end of the strip product 20 is guided by actuation of an apron table 96 to a pinch roll and thence to a coiling station (not shown). Apron table 96 hangs from pivot mountings 97 on the main frame and can be swung toward the pinch roll by actuation of an hydraulic cylinder unit (not shown) after the clean head end has been formed.

[0027] The removable roll cassette 13 is constructed so that the casting rolls 16 can be set up and the nip between them adjusted before the cassette is installed in position in the caster. Moreover when the cassette is installed two pairs of roll biasing units 110, 111 mounted on the main machine frame 11 can be rapidly connected to roll supports on the cassette to provide biasing forces resisting separation of the rolls.

[0028] Roll cassette 13 comprises a large frame 102 which carries the rolls 16 and upper part 103 of the refractory enclosure for enclosing the cast strip below the nip. Rolls 16 are mounted on roll supports 104 which carry roll end bearings (not shown) by which the rolls are mounted for rotation about their longitudinal axis in parallel relationship with one another. The two pairs of roll supports 104 are mounted on the roll cassette frame 102 by means of linear bearings 106 whereby they can slide laterally of the cassette frame to provide for bodily movement of the rolls toward and away from one another thus permitting separation and closing movement between the two parallel rolls.

[0029] Roll cassette frame 102 also carries two adjustable spacers 107 disposed beneath the rolls about a central vertical plane between the rolls and located between the two pairs of roll supports 104 so as to serve as stops limiting inward movement of the two roll supports thereby to define the minimum width of the nip between the rolls. As explained below the roll biasing units

110, 111 are actuable to move the roll supports inwardly against these central stops but to permit outward springing movement of one of the rolls against preset biasing forces.

[0030] Each centralising spacer 107 is in the form of a worm or screw driven jack having a body 108 fixed relative to the central vertical plane of the caster and two ends 109 which can be moved on actuation of the jack, equally in opposite directions to permit expansion and contraction of the jack to adjust the width of the nip while maintaining equidistance spacing of the rolls from the central vertical plane of the caster.

[0031] The caster is provided with two pairs of roll biasing units 110, 111 connected one pair to the supports 104 of each roll 16. The roll biasing units 110 at one side of the machine are fitted with helical biasing springs 112 to provide biasing forces on the respective roll supports 104 whereas the biasing units 111 at the other side of the machine incorporate hydraulic actuators 113. The detailed construction of the biasing units 110, 111 is illustrated in Figures 8 and 9. The arrangement is such as to provide two separate modes of operation. In the first mode the biasing units 111 are locked to hold the respective roll supports 104 of one roll firmly against the central stops and the other roll is free to move laterally against the action of the biasing springs 112 of the units 110. In the alternative mode of operation the biasing units 110 are locked to hold the respective supports 104 of the other roll firmly against the central stops and the hydraulic actuators 113 of the biasing units 111 are operated to provide servo-controlled hydraulic biasing of the respective roll. For normal casting it is possible to use simple spring biasing but for high productivity casting (60 metres per minute and above) it is most desirable to have servo-controlled biasing forces.

[0032] The detailed construction of biasing units 110 is illustrated in Figure 8. As shown in that figure, the biasing unit comprises a spring barrel housing 114 disposed within an outer housing 115 which is fixed to the main caster frame 116 by fixing bolts 117.

[0033] Spring housing 114 is formed with a piston 118 which runs within the outer housing 115. Spring housing 114 can be set alternatively in an extended position as illustrated in Figure 8 and a retracted position by flow of hydraulic fluid to and from the cylinder 118. The outer end of spring housing 114 carries a screw jack 119 operated by a geared motor 120 operable to set the position of a spring reaction plunger 121 connected to the screw jack by a rod 130.

[0034] The inner end of the spring 112 acts on a thrust rod structure 122 which is connected to the respective roll support 104 through a load cell 125. The thrust structure is initially pulled into firm engagement with the roll support by a connector 124 which can be extended by operation of a hydraulic cylinder 123 when the biasing unit is to be disconnected.

[0035] When biasing unit 110 is connected to its respective roll support 104 with the spring housing 114 set

in its extended condition as shown in Figure 8 the position of the spring housing and screwjack is fixed relative to the machine frame and the position of the spring reaction plunger 121 can be set to adjust the compression of the spring 112 and to serve as a fixed adjustment against which the spring can react to apply thrusting force to the thrust structure 102 and directly onto the respective roll support 104. With this arrangement the only relative movement during casting operation is the movement of the roll support 104 and thruster structure 122 as a unit against the biasing spring. Accordingly the spring and the load cell are subjected to only one source of friction load and the load actually applied to the roll support can be very accurately measured by the load cell. Moreover since the biasing unit acts to bias the roll support 104 inwardly against the stop it can be adjusted to preload the roll support with a required spring biasing force before metal actually passes between the casting rolls and that biasing force will be maintained during a subsequent casting operation.

[0036] The detailed construction of biasing units 111 is illustrated in Figure 9. As shown in that figure the hydraulic actuator 113 is formed by an outer housing structure 131 fixed to the machine frame by fixing studs 132 and an inner piston structure 133 which forms part of a thruster structure 134 which acts on the respective roll support 104 through a load cell 137. The thruster structure is initially pulled into firm engagement with the roll support by a connector 135 which can be extended by actuation of a hydraulic piston and cylinder unit 136 when the thruster structure is to be disconnected from the roll support. Hydraulic actuator 113 can be actuated to move the thruster structure 134 between extended and retracted conditions and when in the extended condition to apply a thrust which is transmitted directly to the roll support bearing 104 through the load cell 137. As in the case of the spring biasing units 110 the only movement which occurs during casting is the movement of the roll support and the thruster structure as a unit relative to the remainder of the biasing unit. Accordingly, the hydraulic actuator and the load cell need only act against one source of friction load and the biasing force applied by the unit can be very accurately controlled and measured. As in the case of the spring loaded biasing units, the direct inward biasing of the roll supports against the fixed stop enables preloading of the roll supports with accurately measured biasing forces before casting commences.

[0037] For normal casting the biasing units 111 may be locked to hold the respective roll supports firmly against the central stops simply by applying high pressure fluid to the actuators 113 and the springs 112 of the biasing units 110 may provide the necessary biasing forces on one of the rolls. Alternatively if the biasing units 111 are to be used to provide servo-controlled biasing forces, the units 110 are locked up by adjusting the positions of the spring reaction plungers 121 to increase the spring forces to a level well in excess of the

roll biasing forces required for normal casting. The springs then hold the respective roll carriers firmly against the central stops during normal casting but provide emergency release of the roll in excessive roll separation forces occur.

[0038] Roll cassette frame 102 is supported on four wheels 141 whereby it can be moved to bring it into and out of operative position within the caster. On reaching the operative position the whole frame is lifted by operation of a hoist 143 comprising hydraulic cylinder units 144 and then clamped by operation of horizontal hydraulic cylinder units 145 whereby it is firmly clamped in its operative position. As the cassette frame is raised by operation of the hoist 143 a central centering pin provides accurate longitudinal location of the cassette frame. The operation of the horizontal cylinder units 145 clamps the cassette frame against fixed stops 146 on the main machine frame whereby it is accurately located laterally of the rollers such that the centering jacks or spacers 107 are properly located on the central vertical plane of the caster. This ensures that the rolls are accurately set at equal spacing from the central plane and that the delivery nozzle 19 is also accurately positioned beneath the distributor 18 on the main machine frame.

[0039] The illustrated caster has been advanced by way of example only and it could be modified considerably. For example it would be possible to provide roll biasing units incorporating both springs and hydraulic actuators. However, the separation of the two kinds of actuation is preferred for simplicity of construction and flexibility of operation. It is also not essential to the present invention that the rolls and central stops be mounted on a removable module or cassette and they could be mounted directly on the main machine frame. It is accordingly to be understood that the invention is in no way limited to the constructional details of the illustrated caster and that many modifications and variations will fall within the scope of the appended claims.

Claims

1. Apparatus for continuously casting metal strip comprising a pair of parallel casting rolls (16) forming a nip between them, metal delivery means (18, 19) to deliver molten metal into the nip between the rolls to form a casting pool (30) of molten metal supported on casting roll surfaces immediately above the nip; pool confining means (56) to confine the molten metal in the casting pool against outflow from the ends of the nip; and roll drive means (41) to drive the casting rolls in counter-rotational directions to produce a solidified strip (20) of metal delivered downwardly from the nip characterised in that at least one of the casting rolls (16) is mounted on a pair of moveable roll carriers (104) which allow that one roll (16) to move bodily toward and away from

- the other roll (16), there is an adjustable stop means (107) to limit inward bodily movement of said one roll toward the other; there is a pair of roll biasing units (110 or 111) acting one on each of the pair of moveable roll carriers to bias said one roll (16) bodily inwardly toward the other roll (16); and each roll biasing unit (110 or 111) comprises a thrust transmission structure (122 or 134) connected to the respective roll carrier, a thrust reaction structure (121 or 131) having a set position, thrust means (112 or 113) acting between the thrust reaction structure (121 or 131) and the thrust transmission structure (122 or 134) to exert a thrust on the thrust transmission structure to bias the respective roll carrier (104) inwardly against the limit imposed by the stop means (107).
2. Apparatus as claimed in claim 1, further characterised in that the thrust transmission structure (122 or 134) incorporates a load cell (125 or 137) to monitor the thrust transmitted thereby without any friction generating movement within that structure.
 3. Apparatus as claimed in claim 1 or claim 2, further characterised in that the thrust means (113) comprises a pressure fluid actuator means.
 4. Apparatus as claimed in claim 1 or claim 2, further characterised in that the thrust means (112) comprises a spring acting between the thrust reaction structure (121) and the thrust transmission structure (122).
 5. Apparatus as claimed in claim 4, further characterised in that the thrust reaction structure (121) is adjustable in position to vary said set position whereby to vary the biasing force generated by the spring (112).
 6. Apparatus as claimed in any one of claims 1 to 5, further characterised in that the casting rolls (16) are each mounted on a pair of moveable roll carriers (104) so as to be bodily moveable toward and away from the other roll and the adjustable stop means (107) is effective to limit inward bodily movement of both of the rolls (16).
 7. Apparatus as claimed in claim 6, further characterised in that said pair of roll biasing units is one of two such pairs (110, 111) acting on the pairs of roll carriers (104) to bias both of the rolls inwardly against the limit established by the stop means (107).
 8. Apparatus as claimed in claim 7, further characterised in that the biasing units (110) acting on one of the rolls (16) have thrust means in the form of springs (112) whereas the biasing units (111) acting on the other roll (16) have thrust means in the form of pressure fluid actuators (113).
 9. Apparatus as claimed in any one of claims 6 to 8, further characterised in that the adjustable stop means (107) is disposed beneath the nip and between the roll carriers (104) to serve as a spacer stop for engagement with the roll carriers (104) to pre-set the minimum width of the nip between the rolls and adjustable in width to vary the minimum width of the nip.
 10. Apparatus as claimed in any one of claims 6 to 9, further characterised in that the roll carriers (104) comprise a pair of roll end support structures for each of the rolls disposed generally beneath the ends of the respective roll.
 11. Apparatus as claimed in claim 10, further characterised in that each pair of roll end support structures carries journal bearings mounting the respective roll ends for rotation about a central roll axis.
 12. Apparatus as claimed in claim 10 or claim 11, further characterised in that the adjustable stop means (107) comprises a pair of adjustable stops disposed one between each of the pairs of roll end support structures at the two ends of the roll assembly.
 13. Apparatus as claimed in claim 12, further characterised in that each adjustable stop (107) serves as a centring stop disposed about a central vertical plane through the nip between the rolls and actuable such that it can be expanded and contracted by equal movements to either side of the central plane so as to maintain equal minimum spacing of the rolls from the central plane.
 14. Apparatus as claimed in claim 13, further characterised in that each central stop (107) is comprised of an expansible and contractible mechanical jack.
 15. Apparatus as claimed in any one of claims 1 to 14, further characterised in that the casting rolls (16) and roll carriers (104) are mounted on a roll module (13) installed in and removable from the caster as a unit.
 16. Apparatus as claimed in claim 15, further characterised in that the thrust transmission structure (122 or 134) of each biasing unit (110 or 111) is disconnectable from the respective roll carrier (104) to enable the module (13) to be removed without removing or dismantling the roll biasing units.
